

CPTS 360: Lab Assignment 2

Building a Unix Shell

Notes:

- This is an individual lab.
- You must complete the lab on a Linux environment (either a dedicated machine or VM). Using WSL (Windows Subsystem for Linux) on Windows system is NOT recommended.
- Your submission will be tested on a Linux environment. You will NOT receive any points if your submitted program does not work on a Linux system.
- Start EARLY. The lab may take more time than you anticipated.
- Read the entire document carefully before you start working on the lab.
- The code and other answers you submit MUST be entirely your own work, and you are bound by the WSU Academic Integrity Policy (<https://www.communitystandards.wsu.edu/policies-and-reporting/academic-integrity-policy/>).
- You MAY consult with other students about the conceptualization of the tasks and the meaning of the questions, but you MUST NOT look at any part of someone else's solution or collaborate with anyone.
- You may consult published references or search online archives, provided that you appropriately cite them in your reports/programs.
- The use of artificial intelligence (AI)-generated texts/code-snippets must be CLEARLY DISCLOSED including the prompt used to generate the results and the corresponding outputs the tool(s) provide.

Good Luck!

1 Introduction

The purpose of this assignment is to become more familiar with the concepts of process control and signalling. You will do this by writing a simple Unix shell program that supports job control.

2 General Overview of Unix Shells

A *shell* is an interactive command-line interpreter that runs programs on behalf of the user. A shell repeatedly prints a prompt, waits for a *command line* on *stdin*, and then carries out some action, as directed by the contents of the command line.

The command line is a sequence of ASCII text words delimited by whitespace. The first word in the command line is either the name of a built-in command or the pathname of an executable file. The remaining words are command-line arguments. If the first word is a built-in command, the shell immediately executes the command in the current process. Otherwise, the word is assumed to be the pathname of an executable program. In this case, the shell forks a child process, then loads and runs the program in the context of the

child. The child processes created as a result of interpreting a single command line are known collectively as a *job*. In general, a job can consist of multiple child processes connected by Unix pipes.

If the command line ends with an ampersand "&", then the job runs in the *background*, which means that the shell does not wait for the job to terminate before printing the prompt and awaiting the next command line. Otherwise, the job runs in the *foreground*, which means that the shell waits for the job to terminate before awaiting the next command line. Thus, at any point in time, at most one job can be running in the foreground. However, an arbitrary number of jobs can run in the background.

Unix shells support the notion of *job control*, which allows users to move jobs back and forth between background and foreground, and to change the process state (running, stopped, or terminated) of the processes in a job. Typing `ctrl-c` causes a SIGINT signal to be delivered to each process in the foreground job. The default action for SIGINT is to terminate the process. Similarly, typing `ctrl-z` causes a SIGTSTP signal to be delivered to each process in the foreground job. The default action for SIGTSTP is to place a process in the stopped state, where it remains until it is awakened by the receipt of a SIGCONT signal. Unix shells also provide various built-in commands that support job control. For example:

- `jobs`: List the running and stopped background jobs.
- `bg <job>`: Change a stopped background job to a running background job.
- `fg <job>`: Change a stopped or running background job to a running in the foreground.
- `kill <job>`: Terminate a job.

3 Lab Details

In the lab's Github repository, we provide related files. Type the command `make` to compile and link some test routines. Looking at the `tsh.c` (*tiny shell*) file, you will see that it contains a functional skeleton of a simple Unix shell. To help you get started, we have already implemented the less interesting functions.

Your assignment is to complete the remaining empty functions listed below.

- `eval`: Main routine that parses and interprets the command line.
- `builtin_cmd`: Recognizes and interprets the built-in commands: `quit`, `fg`, `bg`, and `jobs`.
- `do_bgfg`: Implements the `bg` and `fg` built-in commands.
- `waitfg`: Waits for a foreground job to complete.
- `sigchld_handler`: Catches SIGCHLD signals.
- `sigint_handler`: Catches SIGINT (`ctrl-c`) signals.
- `sigtstp_handler`: Catches SIGTSTP (`ctrl-z`) signals.

Each time you modify your `tsh.c` file, type `make` to recompile it.

To run your shell, type `tsh` to the command line:

```
unix> ./tsh
tsh> [type commands to your shell here]
```

You can use the following command to display the helper routing.

```
unix> ./tsh -h
Usage: shell [-hvp]
-h    print this message
-v    print additional diagnostic information
-p    do not emit a command prompt
```

The `tsh` supports Unix job control as mentioned before. For example, typing the command line

```
tsh> jobs
```

causes the shell to execute the built-in `jobs` command. Typing the command line

```
tsh> /bin/ls -l -d
```

runs the `ls` program in the foreground. By convention, the shell ensures that when the program begins executing its main routine

```
int main(int argc, char *argv[])
```

the `argc` and `argv` arguments have the following values:

- `argc == 3`,
- `argv[0] == '/bin/ls'`,
- `argv[1] == '-l'`,
- `argv[2] == '-d'`.

Alternatively, typing the command line

```
tsh> /bin/ls -l -d &
```

runs the `ls` program in the background.

Section 4 presents additional details for job control implementation.

4 The `tsh` Specification

Your `tsh` shell should have the following features:

- The prompt should be the string “`tsh>` ”.
- The command line typed by the user should consist of a name and zero or more arguments, all separated by one or more spaces. If name is a built-in command, then `tsh` should handle it immediately and wait for the next command line. Otherwise, `tsh` should assume that name is the path of an executable file, which it loads and runs in the context of an initial child process (in this context, the term *job* refers to this initial child process).

- `tsh` need not support pipes (`|`) or I/O redirection (`<` and `>`).
- Typing `ctrl-c` (`ctrl-z`) should cause a `SIGINT` (`SIGTSTP`) signal to be sent to the current foreground job, as well as any descendents of that job (e.g., any child processes that it forked). If there is no foreground job, then the signal should have no effect.
- If the command line ends with an ampersand `&`, then `tsh` should run the job in the background. Otherwise, it should run the job in the foreground.
- Each job can be identified by either a process ID (PID) or a job ID (JID), which is a positive integer assigned by `tsh`. JIDs should be denoted on the command line by the prefix `%`. For example, `%5` denotes JID 5, and `5` denotes PID 5. We have provided you with all of the routines you need for manipulating the job list.
- `tsh` should support the following built-in commands:
 - The `quit` command terminates the shell.
 - The `jobs` command lists all background jobs.
 - The `bg <job>` command restarts `<job>` by sending it a `SIGCONT` signal, and then runs it in the background. The `<job>` argument can be either a PID or a JID.
 - The `fg <job>` command restarts `<job>` by sending it a `SIGCONT` signal, and then runs it in the foreground. The `<job>` argument can be either a PID or a JID.
- `tsh` should reap all of its zombie children. If any job terminates because it receives a signal that it didn't catch, then `tsh` should recognize this event and print a message with the job's PID and a description of the offending signal.

5 Checking Your Work

We have provided some tools to help you check your work.

Shell driver. The `sdriver.pl` program executes a shell as a child process, sends it commands and signals as directed by a *trace file*, and captures and displays the output from the shell.

Use the `-h` argument to find out the usage of `sdriver.pl`:

```
unix> ./sdriver.pl -h
Usage: sdriver.pl [-hv] -t <trace> -s <shellprog> -a <args>
Options:
  -h          Print this message
  -v          Be more verbose
  -t <trace>   Trace file
  -s <shell>   Shell program to test
  -a <args>    Shell arguments
  -g          Generate output for autograder
```

We have also provided 16 trace files (`trace{01-16}.txt`) that you will use in conjunction with the shell driver to test the correctness of your shell. The lower-numbered trace files do very simple tests, and the higher-numbered tests do more complicated tests.

You can run the shell driver on your shell using trace file `trace01.txt` (for instance) by typing:

```
unix> ./sdriver.pl -t trace01.txt -s ./tsh -a "-p"
```

(the `-a "-p"` argument tells your shell not to emit a prompt), or

```
unix> make test01
```

Reference Output. For your reference, `tshref.out` gives the output of the reference solution on all races. This might be more convenient for you than manually running the shell driver on all trace files.

The neat thing about the trace files is that they generate the same output you would have gotten had you run your shell interactively (except for an initial comment that identifies the trace). For example:

```
unix> make test15
./sdriver.pl -t trace15.txt -s ./tsh -a "-p"
#
# trace15.txt - Putting it all together
#
tsh> ./bogus
./bogus: Command not found.
tsh> ./myspin 10
Job (9721) terminated by signal 2
tsh> ./myspin 3 &
[1] (9723) ./myspin 3 &
tsh> ./myspin 4 &
[2] (9725) ./myspin 4 &
tsh> jobs
[1] (9723) Running    ./myspin 3 &
[2] (9725) Running    ./myspin 4 &
tsh> fg %1
Job [1] (9723) stopped by signal 20
tsh> jobs
[1] (9723) Stopped    ./myspin 3 &
[2] (9725) Running    ./myspin 4 &
tsh> bg %3
%3: No such job
tsh> bg %1
[1] (9723) ./myspin 3 &
tsh> jobs
[1] (9723) Running    ./myspin 3 &
[2] (9725) Running    ./myspin 4 &
tsh> fg %1
tsh> quit
bass>
```

6 Hints

- Follow the lectures on Exceptional Control Flow, Process, Signal, and read related textbook chapter.
- Use the trace files to guide the development of your shell. Starting with `trace01.txt`, make sure that your shell produces the *identical* output as the reference shell. Then move on to trace file `trace02.txt`, and so on.
- The `waitpid`, `kill`, `fork`, `execve`, `setpgid`, and `sigprocmask` functions will come in very handy. The `WUNTRACED` and `WNOHANG` options to `waitpid` will also be useful.
- When you implement your signal handlers, be sure to send `SIGINT` and `SIGTSTP` signals to the entire foreground process group, using “-pid” instead of “pid” in the argument to the `kill` function. The `sdriver.pl` program tests for this error.
- One of the tricky parts of the assignment is deciding on the allocation of work between the `waitfg` and `sigchld_handler` functions. We recommend the following approach:
 - In `waitfg`, use a busy loop around the `sleep` function.
 - In `sigchld_handler`, use exactly one call to `waitpid`.

While other solutions are possible, such as calling `waitpid` in both `waitfg` and `sigchld_handler`, these can be very confusing. It is simpler to do all reaping in the handler.

- In `eval`, the parent must use `sigprocmask` to block `SIGCHLD` signals before it forks the child, and then unblock these signals, again using `sigprocmask` after it adds the child to the job list by calling `addjob`. Since children inherit the blocked vectors of their parents, the child must be sure to then unblock `SIGCHLD` signals before it execs the new program.

The parent needs to block the `SIGCHLD` signals in this way in order to avoid the race condition where the child is reaped by `sigchld_handler` (and thus removed from the job list) *before* the parent calls `addjob`.

- Programs such as `more`, `less`, `vi`, and `emacs` do strange things with the terminal settings. Don't run these programs from your shell. Stick with simple text-based programs such as `/bin/ls`, `/bin/ps`, and `/bin/echo`.
- When you run your shell from the standard Unix shell, your shell is running in the foreground process group. If your shell then creates a child process, by default that child will also be a member of the foreground process group. Since typing `ctrl-c` sends a `SIGINT` to every process in the foreground group, typing `ctrl-c` will send a `SIGINT` to your shell, as well as to every process that your shell created, which obviously isn't correct.

Here is the workaround: After the `fork`, but before the `execve`, the child process should call `setpgid(0, 0)`, which puts the child in a new process group whose group ID is identical to the child's PID. This ensures that there will be only one process, your shell, in the foreground process group. When you type `ctrl-c`, the shell should catch the resulting `SIGINT` and then forward it to the appropriate foreground job (or more precisely, the process group that contains the foreground job).

7 Deliverable

1. Complete the implementation of `tsh.c`.
2. Write a short report (no more than 2 pages, 11 points Times font, 1 inch margin) summarizing the key ideas (including your thought process) you used to implement each of the seven functions (i.e., `eval`, `builtin_cmd`, `do_bgfg`, `waitfg`, `sigchld_handler`, `sigint_handler`, and `sigstp_handler`) in `tsh.c`.

Complete the implementation of `tsh.c`.

Your score will be computed out of a maximum of **100 points** based on the following distribution:

- Correctness. **[80 Points]**
 - 16 trace files at **5 points** each.
- Code organization and comments. **[10 Points]**
 - We expect you to have proper comments **[5 Points]** and
 - Check the return value of EVERY system call **[5 Points]**.
- Your report in a PDF form. **[10 Points]**
 - Your PDF filename should be `lab2_lastname.pdf`, where `lastname` is your surname. Include your **full name** and **WSU ID** inside the report. We will deduct 5 points if the filename/formatting/contents does not follow this convention.

Your solution shell will be tested for correctness on a Linux machine, using the same shell driver and trace files that were included in your lab directory. Your shell should produce **identical** output on these traces as the reference shell, with only two exceptions:

- The PIDs can (and will) be different.
- The output of the `/bin/ps` commands in `trace11.txt`, `trace12.txt`, and `trace13.txt` will be different from run to run. However, the running states of any `mysplit` processes in the output of the `/bin/ps` command should be identical.

8 Submission Guidelines

Commit and push your work on GitHub Classroom Lab 2 repository. **Make sure you can successfully push commits on GitHub Classroom (last minute excuses will not be considered)**. Get the Git commit id of your work by running the command: `git log -1 --format=oneline`. Paste the commit id (the hexadecimal string) to the corresponding lab assignment section of Canvas. Check the course website for additional details.

Note: On Canvas, you can submit any commit id (not necessarily the last one) from your Github Classroom Git history. You can also submit as many times as you want. However, we will grade the last commit id submitted to Canvas before the deadline.

Your work on GitHub Classroom will not be considered for grading unless you confirm your commit ID on Canvas. Hence, **You will NOT receive any points if you failed to submit your commit ID on Canvas by the due date.**
